ABSTRACT

In this paper we used, the Dai-Yuan nonlinear conjugate gradient (DYCG) method, to the three-term conjugate gradient (TDYCG) method and the derivation of the method, based on the Perry's conjugacy condition. The global convergence was proved, with Wolfe line search. Numerical experiments are reported and shows the presented method outperforming, some other three-term CG methods.

KEYWORDS: Three-Term Conjugate Gradient, conjugate gradient algorithms, Of quasi-Newton methods

INTRODUCTION

We consider the unconstrained optimization problem:

\[ \min f(x), \quad x \in \mathbb{R}^n \]  \hspace{1cm} (1.1)

Where \( f : \mathbb{R}^n \rightarrow \mathbb{R} \) is a continuously differentiable function and bounded below the nonlinear conjugate gradient method is an iterative method whereby at the \((k+1)\)th iteration \( x_{k+1} \) is given by:

\[ x_{k+1} = x_k + \alpha_k d_k \]  \hspace{1cm} (1.2)

Where \( d_k \) denotes the search direction and \( \alpha_k \) is the step length. The search direction \( d_{k+1} \) is calculated by

\[ d_{k+1} = -g_{k+1} + \beta_{k+1} d_k, \quad d_1 = -g_1, \quad k=0,1,..... \]  \hspace{1cm} (1.3)

In (1.3) the quantity \( g_k = \nabla f(x_k) \) denotes the gradient of \( f \) at \( x_k \), while \( \beta_{k+1} \) is scalar which can be defined by

\[ \beta_{k+1}^{PR} = \frac{g_k^T g_{k+1} g_{k+1}^T g_k}{g_k^T g_k}, \quad \beta_{k+1}^{DY} = \frac{g_k^T g_{k+1}}{d_k^T y_k}, \quad \beta_{k+1}^{CD} = -\frac{g_{k+1}^T g_{k+1}}{d_k^T g_k} \]  \hspace{1cm} (1.4)

\[ \beta_{k+1}^{FR} = \frac{g_k^T g_{k+1}^T g_{k+1}}{g_k^T g_k}, \quad \beta_{k+1}^{HS} = \frac{g_{k+1}^T y_k}{d_k^T y_k} \]
Or by other formula (e.g. see [1,2,7]). The corresponding method is respectively called FR(Fletcher-Reeves[6]),DY(Dai-Yuan[3]),CD(conjugate-Decent[7]),PR(Polak-Ribiere[11]),HS(HestenesStiefel[9]),respectively.

Where $\|\|_\|$ means the Euclidean norm. The line search in conjugate gradient algorithms is often based on the general Wolfe conditions [13,14]

$$f(x_k + \alpha_k d_k) \leq f(x_k) + \delta \alpha_k d_k$$  \hspace{1cm} (1.5)

$$g^T_{k+1} d_k \geq \sigma g^T_k d_k$$ \hspace{1cm} (1.6)

Where $d_k$ is a descent direction and $0 < \delta < \sigma < 1$. However, for some conjugate gradient algorithms, stronger Wolfe (SW) condition used, defined by equation (1.5) and:

$$\left| g^T_{k+1} d_k \right| \geq -\sigma g^T_k d_k$$  \hspace{1cm} (1.7)

Are needed to ensure the convergence and to enhance the stability.

The pure conjugacy condition is represented by the form

$$d^T_{k+1} y_k = 0$$  \hspace{1cm} (1.8)

For nonlinear conjugate gradient methods. The extension of the conjugacy condition was studied by Perry [10], he tried to accelerate the conjugate gradient method by incorporating the second-order information into it specifically, he used the secant condition

$$H_{k+1} y_k = s_k$$  \hspace{1cm} (1.9)

Of quasi-Newton methods, where asymmetric matrix $H_{k+1}$ is an approximation to the inverse Hessian. For quasi-Newton methods, the search direction $d_{k+1}$ can be calculated in the form

$$d_{k+1} = -H_{k+1} g_{k+1}$$  \hspace{1cm} (1.10)

By (1.9) and (1.10) the relation

$$d^T_{k+1} y_k = -(H_{k+1} g_{k+1})^T y_k = -g^T_{k+1} (H_{k+1} y_k) = -g^T_{k+1} s_k$$ \hspace{1cm} (1.11)

Holds By taking this relation into account, Perry replaced the conjugacy condition (1.8) by the condition

$$d^T_{k+1} y_k = -g^T_{k+1} s_k$$ \hspace{1cm} (1.12)

Recently Zhang, Zou and Li [15, 16], proposed the following three-term conjugate gradient methods
New Three-Term Conjugate Gradient Method for Solving Unconstrained Optimization Problems

\[ d_{k+1} = -g_{k+1} + \beta^{FR}_k d_k - \gamma^{(1)}_k g_k \]  
\( k \) \( k \) \( k \) \( k \)

\[ d_{k+1} = -g_{k+1} + \beta^{PR}_k d_k - \gamma^{(2)}_k g_k \]  
\( k \) \( k \) \( k \) \( k \)

\[ d_{k+1} = -g_{k+1} + \beta^{HS}_k d_k - \gamma^{(3)}_k g_k \]  
\( k \) \( k \) \( k \) \( k \)

\[ d_{k+1} = -g_{k+1} + \beta^{DY}_k d_k + \gamma^{(4)}_k g_k \]  
\( k \) \( k \) \( k \) \( k \)

Where

\[ \gamma^{(1)}_k = \frac{\mathbf{g}_k^T d_k}{\mathbf{g}_k^T \mathbf{g}_k}, \quad \gamma^{(2)}_k = \frac{\mathbf{g}_k^T d_k}{\mathbf{g}_k^T \mathbf{g}_k}, \quad \gamma^{(3)}_k = \frac{\mathbf{g}_k^T d_k}{\mathbf{y}_k^T \mathbf{d}_k}, \quad \gamma^{(4)}_k = \frac{-\mathbf{g}_k^T \mathbf{g}_k}{\mathbf{y}_k^T \mathbf{y}_k} \]  
\( k \) \( k \) \( k \) \( k \) \( k \) \( k \) \( k \) \( k \)

The rest of the paper is organized as follows: In section 2, we presented a new three-term conjugate gradient (TKLCG) method, which was obtained by modification of the Khalil-Linda CG method. Section 3, presents the global convergence of the proposed algorithm. In section 4, some numerical results and comparisons with some other three-term conjugate gradient methods, were presented.

**NEW THREE-TERM CG-METHOD (TKLCG)**

In this section, we derive a new three-term conjugate gradient algorithm, for unconstrained optimization which is generalization to, the Dai-Yuan CG method. Consider the following three-term search direction

\[ d_{k+1} = -\theta_{k+1} \mathbf{s}_{k+1} + \beta^D_k \mathbf{s}_k + \gamma^{KL}_k \mathbf{y}_k \]  
\( k \) \( k \) \( k \) \( k \) \( k \) \( k \) \( k \) \( k \) \( k \)

If we use inexact line search and Perry conjugacy condition (1.12), we get from (2.1) the following value for \( \theta_{k+1} \)

\[ \theta_{k+1} = 1 + \frac{\mathbf{g}_k^T \mathbf{s}_k}{\mathbf{g}_{k+1}^T \mathbf{y}_k} \]  
\( k \) \( k \) \( k \) \( k \) \( k \) \( k \) \( k \) \( k \) \( k \)

Therefore our new three-term (TKLCG) conjugate gradient algorithm can be defined as

\[ d_{k+1} = \left( 1 + \frac{\mathbf{g}_k^T \mathbf{s}_k}{\mathbf{g}_k^T \mathbf{y}_k} \right) \mathbf{g}_{k+1} + \frac{\mathbf{g}_{k+1} \mathbf{g}_k^T \mathbf{s}_k - \mathbf{g}_k^T \mathbf{g}_k}{\mathbf{y}_k^T \mathbf{y}_k} \mathbf{y}_k \]  
\( k \) \( k \) \( k \) \( k \) \( k \) \( k \) \( k \) \( k \) \( k \) \( k \) \( k \) \( k \) \( k \)

We see from (2.3), for quadratic convex function with exact line search the above search direction reduces to the Fletcher CD method i.e.

\[ d_{k+1} = -\mathbf{g}_{k+1} + \frac{\mathbf{g}_{k+1} \mathbf{s}_k}{\mathbf{g}_k^T \mathbf{s}_k} \]  
\( k \) \( k \) \( k \) \( k \) \( k \) \( k \) \( k \) \( k \) \( k \)
(TKLCG) Algorithm

Step 1. Given $x_0 \in R^n$, $\epsilon > 0$, $d_1 = -g_1$; $k = 1$

Step 2. If $\|g_{k+1}\| \leq \epsilon$, stop, else go to Step 3

Step 3. Find $\alpha_k$ satisfying Wolfe condition (1.5) and (1.6).

Step 4. Compute a new iterative $x_{k+1}$ by $x_{k+1} = x_k + \alpha_k d_k$.

Step 5. Compute $\beta_{DY}^k$, $\gamma_{k+1}$ and $\theta_{k+1}$ from (2.2) $d_{k+1} = -\theta_{k+1} g_{k+1} + \beta_{DY}^k s_k + \gamma_{k+1}^k y_k$ and set $k = k + 1$ go to step 2.

3. DESCENT PROPERTY AND GLOBAL CONVERGENCE ANALYSIS

Next we will show that our three-term CG (2.3)-method satisfies the descent property and global converges.

Theorem 3.1. Let $\{x_k\}$ and $\{d_k\}$ be generated by the equation (1.2), (2.3) and $\alpha_k$ satisfies Wolfe line search conditions (1.5) and (1.6), then $d_k^T g_k < 0$ hold for all $k \geq 1$.

Proof. The conclusion can be proved by induction. When $k = 1$, we have $d_1^T g_1 \geq -\|g_1\|^2 < 0$

Suppose that $d_k^T g_k < 0$ hold for all $k$. From (2.3) we have

$$d_{k+1}^T g_{k+1} = \left(1 + \frac{g_{k+1}^T s_k}{g_{k+1}^T y_k}ight) g_{k+1}^T g_{k+1} + \frac{g_{k+1}^T s_k}{y_k^T s_k} g_{k+1}^T g_{k+1} - \frac{g_{k+1}^T g_k}{y_k^T y_k} g_{k+1}^T y_k$$

$$d_{k+1}^T g_{k+1} = \left(1 + \frac{g_{k+1}^T s_k}{g_{k+1}^T y_k}ight) \|g_{k+1}\|^2 + \frac{g_{k+1}^T s_k}{y_k^T s_k} \|g_{k+1}\|^2 - \frac{g_{k+1}^T g_k}{y_k^T y_k} g_{k+1}^T y_k$$

$$d_{k+1}^T g_{k+1} = \left(1 + \frac{g_{k+1}^T s_k}{g_{k+1}^T y_k}ight) g_{k+1}^T g_{k+1} - \frac{g_{k+1}^T g_k}{y_k^T y_k} g_{k+1}^T y_k$$

$$d_{k+1}^T g_{k+1} = \left(1 + \frac{g_{k+1}^T s_k}{g_{k+1}^T y_k}ight) \|g_{k+1}\|^2 - \frac{g_{k+1}^T g_k}{y_k^T y_k} g_{k+1}^T y_k$$

$$d_{k+1}^T g_{k+1} = \left(1 + \frac{g_{k+1}^T s_k}{g_{k+1}^T y_k}ight) g_{k+1}^T g_{k+1} + \frac{g_{k+1}^T g_k}{y_k^T y_k} g_{k+1}^T y_k$$

Impact Factor (JCC): 5.9876

NAAS Rating: 3.76
\[
\begin{align*}
\therefore g_{k+1}^T g_k & \leq \|g_{k+1}\|^2 \\
\therefore d_{k+1}^T g_{k+1} & \leq \left(1 + \frac{g_{k+1}^T s_k}{y_k^T s_k} \frac{g_k + s_k}{y_k s_k} \right) \|g_{k+1}\|^2 - \frac{g_{k+1}^T s_k}{y_k^T s_k} \|g_{k+1}\|^2 + \frac{g_{k+1}^T g_k + s_k}{y_k^T s_k} \|g_{k+1}\|^2 \\
\therefore d_{k+1}^T g_{k+1} & \leq \left(1 + \frac{g_{k+1}^T s_k}{y_k^T s_k} \frac{g_k + s_k}{y_k s_k} \right) \|g_{k+1}\|^2 \\
\end{align*}
\]

By Wolfe condition \(y_k^T s_k > 0\) and let \(0 \leq \frac{g_{k+1}^T s_k}{y_k^T s_k} \leq 1\), then we can deduced that \(d_{k+1}^T g_{k+1} < 0\) holds for all \(k \geq 1\).

To prove the global convergence we need the following assumption [8]

H1. The objective function \(f\) is bound below in the level set \(\Omega = \{x \in \mathbb{R}^n : f(x) \leq \gamma\}\) where \(x_1\) the starting point is.

H2. \(f\) is continuously differentiable in a neighborhood \(\mathcal{N}\) of \(\Omega\) and its gradient \(g\) is Lipchitz continuous, there exist \(L > 0\) such that
\[
\|g(x) - g(y)\| \leq L\|x - y\| \quad \forall x, y \in \mathcal{N}
\]

H3. \(f\) is uniformly convex function, then there exists a constant \(\mu > 0\) such that
\[
y_k^T s_k \geq \mu \|s_k\|^2 \quad \text{and} \quad \mu \|s_k\|^2 \leq y_k^T s_k \leq L \|s_k\|^2
\]

On the other hand, under assumption [10], it is clear that there exist positive constant \(B\) such
\[
\|x\| \leq B \quad \forall x \in \Omega \quad (3.3)
\]
\[
\gamma \leq \|g(x)\| \leq \gamma, \forall x \in \Omega \quad (3.4)
\]

Lemma (1) [8]

Suppose that Assumption [10] and equation (3.3) hold. Consider any conjugate gradient method in from (1.2) and (1.3), where \(d_k\) is a descent direction and \(\alpha_k\) is obtained by the strong Wolfe (SW). If
\[ \sum_{k > 1} \frac{1}{\|d_{k+1}\|^2} = \infty \quad (3.5) \]

Then we have

\[ \lim_{k \to \infty} \left( \inf \|g_k\| \right) = 0 . \]

More details can be found in [1,4and12]

Theorem (1)

Suppose that, assumption [8], equation (3.3) and the descent condition hold. Consider a conjugate gradient method in the equation (2.3) where \( \alpha_k \) is computed from Wolfe line search condition (1.5) and (1.6) If the objective function is uniformly on set \( \Omega \), then \( \lim_{k \to \infty} \left( \inf \|g_k\| \right) = 0 . \)

\[ (3.6) \]

Proof

\[ d_{k+1} = -\theta_{k+1} g_{k+1} + \beta_k^{DY} s_k + \gamma_{k+1}^{KL} y_k \]

Where

\[ \|d_{k+1}\|^2 = \left\| -\theta_{k+1} g_{k+1} + \beta_k^{DY} s_k + \gamma_{k+1}^{KL} y_k \right\|^2 \quad (3.7) \]

Using Cauchy Schwartz together with inequality (3.3) we get

\[ \|d_{k+1}\|^2 \leq \theta_{k+1} \|g_{k+1}\|^2 + \beta_k^{DY} \|s_k\|^2 + \gamma_{k+1}^{KL} \|y_k\|^2 \quad (3.8) \]

\[ \|d_{k+1}\|^2 \leq \theta_{k+1} \|g_{k+1}\|^2 + \beta_k^{DY} \|s_k\|^2 + \gamma_{k+1}^{KL} L \|s_k\|^2 \quad (3.9) \]

Let \( M = \|y_k\|^2 \) then we get

\[ \|d_{k+1}\|^2 \leq \theta_{k+1} \|g_{k+1}\|^2 + \beta_k^{DY} M + \gamma_{k+1}^{KL} LM \quad (3.10) \]

\[ \|d_{k+1}\|^2 \leq \theta_{k+1} \|g_{k+1}\|^2 + M \left( \beta_k^{DY} + \gamma_{k+1}^{KL} L \right) \quad (3.11) \]

By Using Assumption [8] then we get

\[ \|d_{k+1}\|^2 \leq \theta_{k+1} \gamma^2 + M \left( \beta_k^{DY} + \gamma_{k+1}^{KL} L \right) \quad (3.12) \]
Let \( F = \theta_{k+1} \left( \gamma^2 \right)^2 + M \gamma^2 (\beta_k^{DY} + \gamma_k^{KL1} L) \) then we get

\[
\left\| d_{k+1} \right\|^2 \leq F \frac{1}{\gamma^2}
\] (3.13)

\[
\sum_{k=1}^{\infty} \frac{1}{\left\| d_{k+1} \right\|^2} \geq \frac{1}{F} \gamma^2 \sum_{k=1}^{\infty} 1 = \infty
\] (3.14)

By Using Lemma (1) then we get

\[
\lim_{k \to \infty} \left( \inf \left\| g_k \right\| \right) = 0
\] (3.15)

4. NUMERICAL RESULTS AND COMPARISONS

In this section, we compared the performance of new formal \( \theta_{k+1} \), and developed a new three-term method of conjugate gradient method, to other classical conjugate gradient method Dai-Yuan (DY) and Khalil-linda (KL1) algorithms. We have selected 20 large scale unconstrained optimization problems, for each test problems taken from Andrie, (2008) [2]. For each test function, we have considered numerical experiments with the number of variables \( n=100, \ldots, 1000 \). These two new versions were compared with well-known conjugate gradient algorithm, Dai-Yuan (DY) and Khalil-linda (KL1) algorithms. All these algorithms were implemented with standard Wolfe conditions (1.5) and (1.6).

In all these cases, the stopping criteria is the \( \left\| g_k \right\| = 10^{-6} \). All codes were written in double precision, FORTRAN language, with F77 default compiler settings. The test functions usually start the point standards initially summarizing numerical results for 730 functions, recorded in the Table (4.1). The results for the 730 functions, explained in Figure (1), (2) and (3), the performance profile, by Dolan and More’ [5] was used, to display the performance of the Generalized Dai-Yuan Nonlinear Conjugate Gradient algorithm, with Dai-Yuan (DY) and Khalil-linda (KL1) algorithms. Define \( P=730 \) as the whole set of \( n_p \) test problems and \( S=3 \) the set of the interested solvers. Let \( l_{p,s} \), be the number of objective function evaluations, required by solver \( S \) for problem \( P \). Define the performance ratio as

\[
r_{p,s} = \frac{l_{p,s}}{l_s}
\] (4.1)

Where \( l_{p,s}^* = \min \left\{ l_{p,s} : s \in S \right\} \). It is obvious that \( r_{p,s} \geq 1 \) for all \( p,s \). If a solver fails to solve a Problem, the ratio \( r_{p,s} \) is assigned to be a large number \( M \). The performance profile for each solver \( S \) is defined as the following cumulative distribution function for performance ratio \( r_{p,s} \).
\[ \rho_s(\tau) = \frac{\text{size}\{p \in P : r_{p,s} \leq \tau\}}{n_p} \]  

(4.2)

Obviously, \( \rho_s (1) \) represents the percentage of problems, for which solver \( S \) is the best. See figure [5] for more details, about the performance profile. The performance profile can also be used to analyze, the number of iterations, the number of gradient evaluations and the cpu time. Besides, to get a clear observation, we give the horizontal coordinate, a log-scale.

The numerical results show the efficiency comparisons, with some other three-term conjugate gradient methods.
