ABSTRACT

Load Balancing is a method to distribute workload across one or more servers, network interfaces, hard drives, or other computing resources. Load balancing in the cloud differs from classical thinking on load- balancing architecture and implementation by using commodity servers to perform the load balancing. We design and implement a simple model which decreases the migration time of virtual machines by shared camera.

KEYWORDS: Software as a Service (SaaS), Infrastructure as a Service (IaaS), Platform as a Service (PaaS)
